Features

- Selectable conversion gain
- Selectable corner frequency
- Compensation for capacitive input sources
- Adjustable power settings
- Selectable input reference voltage

General Description

The Trans-Impedance Amplifier (TIA) component provides an opamp-based current-to-voltage conversion amplifier with resistive gain and user-selected bandwidth. It is derived from the SC/CT block.

The TIA is used to convert an external current to a voltage. Typical applications include the measurement of sensors with current outputs such as photodiodes. The conversion gain of the TIA is expressed in ohms, with the available range between 20 k\(\Omega\) and 1.0 M\(\Omega\). Current output sensors, such as photodiodes, often have substantial output capacitance. This requires shunt feedback capacitance in the TIA to guarantee stability. The TIA has a programmable feedback capacitor to meet this need and provide bandwidth limiting to reduce broadband noise.

Input/Output Connections

This section describes the various input and output connections for the TIA. An asterisk (*) in the list of I/Os indicates that the I/O may be hidden on the symbol under the conditions listed in the description of that I/O.

lin – Analog

The lin is the input signal terminal. It is the sum of currents from the global inputs, which may include signals from a current output DAC.

**Note** This terminal name is I\(\text{in}\) (uppercase i) not l\(\text{i}\) (lowercase l).
Vref – Analog
Vref is the input terminal for a reference signal. The reference may be an internal reference, internal VDAC value, or external signal.

Vout – Analog
Vout is the output signal terminal. Vout is determined by the following equation, where $R_{FB}$ is resistive feedback:

$$V_{out} = V_{ref} - I_{in} \times R_{FB}$$

Positive (from source) currents result in output voltage that is negative with respect to Vref. Negative (into source) currents result in output voltage that is positive with respect to Vref.

Component Parameters
Drag a TIA component onto your design and double-click it to open the Configure dialog.
Capacitive_Feedback
This sets the capacitive feedback for the TIA. The capacitive feedback can be set to None, 1.3 pF, 3.3 pF, or 4.6 pF (default). The –3 dB frequency for the TIA is calculated from the product of the values of resistive and capacitive feedback components.

Power
This sets the initial drive power of the TIA. The power determines the speed with which the TIA reacts to changes in the input signal. There are four power settings; Minimum Power, Low Power, Medium Power (default) and High Power. The Minimum Power setting results in the slowest response time and High Power the fastest. Minimum and Low Power settings have reduced drive currents and are not suitable for the lower values of feedback resistor.

Resistive_Feedback
This sets the nominal resistive feedback for the TIA. The resistive feedback may be selected from the following set of allowed values (in ohms): 20k (default), 30k, 40k, 80k, 120k, 250k, 500k and 1000k.

-3 db Frequency
This combobox is used to display the calculated value of bandwidth. This value depends on Resistor_Feedback, Capacitive_Feedback values and Power settings.

Application Programming Interface
Application Programming Interface (API) routines allow you to configure the component using software. The following table lists and describes the interface to each function. The subsequent sections cover each function in more detail.

By default, PSoC Creator assigns the instance name “TIA_1” to the first instance of a component in a given design. It can be renamed to any unique value that follows the syntactic rules for identifiers. The instance name becomes the prefix of every global function name, variable and constant symbol. For readability, the instance name used in the following table is “TIA.”

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIA_initVar</td>
<td>Indicates whether the TIA has been initialized. The variable is initialized to 0 and set to 1 the first time TIA_Start() is called. This allows the component to restart without reinitialization after the first call to the TIA_Start() routine. If reinitialization of the component is required, then the TIA_Init() function can be called before the TIA_Start() or TIA_Enable() function.</td>
</tr>
</tbody>
</table>

void TIA_Start(void)

Description: Performs all of the required initialization for the component and enables power to the amplifier. The first time the routine is executed, the resistive and capacitive feedback and amplifier power are set based on the values provided during configuration. When called to restart the TIA following a TIA_Stop() call, the current component parameter settings are retained.

Parameters: None

Return Value: None

Side Effects: None

void TIA_Stop(void)

Description: Powers down TIA to its lowest power state and disables output.

Note: This API is not recommended for use on PSoC 5 silicon. This device has a defect that causes connections to several analog resources to be unreliable when not powered. The unreliability manifests itself in silent failures (for example, unpredictably bad results from analog components) when the component using that resource is stopped. When using this silicon, all analog components in a design should be powered up (by calling their respective _Start() APIs, for instance TIA_Start()) at all times. Do not call the TIA_Stop() APIs.

Parameters: None

Return Value: None

Side Effects: Does not affect power, resistive or capacitive feedback settings
void TIA_SetPower(uint8 power)

**Description:** Sets the drive power to one of four settings; minimum, low, medium, or high.

**Parameters:**
- uint8 power: See the following table for valid power settings.

<table>
<thead>
<tr>
<th>Power Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIA_MINPOWER</td>
<td>Minimum active power and slowest reaction time</td>
</tr>
<tr>

<td>Feedback resistor = 120k</td>
</tr>
<tr>
<td>TIA_RES_FEEDBACK_250K</td>
<td>Feedback resistor = 250k</td>
</tr>
<tr>
<td>TIA_RES_FEEDBACK_500K</td>
<td>Feedback resistor = 500k</td>
</tr>
<tr>
<td>TIA_RES_FEEDBACK_1000K</td>
<td>Feedback resistor = 1000k</td>
</tr>
</tbody>
</table>

**Return Value:** None

**Side Effects:** None
void TIA_SetCapFB(uint8 cap_feedback)
  Description: Set the amplifier capacitive feedback value.
  Parameters:  
                uint8 cap_feedback: See the following table for valid capacitive feedback settings.

<table>
<thead>
<tr>
<th>Gain Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIA_CAP_FEEDBACK_NONE</td>
<td>No capacitive feedback</td>
</tr>
<tr>
<td>TIA_CAP_FEEDBACK_1_3PF</td>
<td>Feedback capacitor = 1.3 pF</td>
</tr>
<tr>
<td>TIA_CAP_FEEDBACK_3_3PF</td>
<td>Feedback capacitor = 3.3 pF</td>
</tr>
<tr>
<td>TIA_CAP_FEEDBACK_4_6PF</td>
<td>Feedback capacitor = 4.6 pF</td>
</tr>
</tbody>
</table>

  Return Value: None
  Side Effects: None

void TIA_Sleep(void)
  Description: This is the preferred API to prepare the component for sleep. The TIA_Sleep() function saves
               the current component state. Then it calls the TIA_Stop() function and calls TIA_SaveConfig() to
               save the hardware configuration.
               Call the TIA_Sleep() function before calling the CyPmSleep() or the CyPmHibernate() function. Refer to
               the PSoC Creator System Reference Guide for more information about power management functions.
  Parameters: None
  Return Value: None
  Side Effects: None

void TIA_Wakeup(void)
  Description: This is the preferred routine to restore the component to the state when TIA_Sleep() was
               called. The TIA_Wakeup() function calls the TIA_RestoreConfig() function to restore the
               configuration. If the component was enabled before the TIA_Sleep() function was called, the
               TIA_Wakeup() function will also re-enable the component.
  Parameters: None
  Return Value: None
  Side Effects: Calling the TIA_Wakeup() function without first calling the TIA_Sleep() or TIA_SaveConfig() function
               may produce unexpected behavior.
void TIA_Init(void)

Description: Initializes or restores the component according to the customizer Configure dialog settings. It is not necessary to call TIA_Init() because the TIA_Start() routine calls this function and is the preferred method to begin component operation.

Parameters: None

Return Value: None

Side Effects: All registers will be set to values according to the customizer Configure dialog.

void TIA_Enable(void)

Description: Activates the hardware and begins component operation. It is not necessary to call TIA_Enable() because the TIA_Start() routine calls this function, which is the preferred method to begin component operation.

Parameters: None

Return Value: None

Side Effects: None

void TIA_SaveConfig(void)

Description: Empty function. Provided for future use.

Parameters: None

Return Value: None

Side Effects: None

void TIA_RestoreConfig(void)

Description: Empty function. Provided for future use.

Parameters: None

Return Value: None

Side Effects: None

Sample Firmware Source Code

PSoC Creator provides many example projects that include schematics and example code in the Find Example Project dialog. For component-specific examples, open the dialog from the Component Catalog or an instance of the component in a schematic. For general examples,
open the dialog from the Start Page or File menu. As needed, use the Filter Options in the dialog to narrow the list of projects available to select. Refer to the “Find Example Project” topic in the PSoC Creator Help for more information.

Functional Description

The TIA is constructed from a generic SC/CT block. The topology is an opamp with a selectable feedback resistor from the output to the inverting input. Optionally, a selectable feedback capacitor can also be connected between the output and the inverting input. Figure 1 shows the two possible TIA configurations.

Figure 1. TIA Configurations

The output voltage is controlled by adjusting the R_FB feedback resistor (see Figure 2). R_FB can be set to one of 8 values, between 20k and 1000k ohms, selectable in either the parameter dialog or using the TIA_SetResFB() API function.

Figure 2. TIA Schematic

The DC output level can be adjusted by adding current to the lin terminal. Positive current (into the terminal) pushes the output negative; negative current (pulling current from the terminal) pushes the output positive. The source of the current can be an internal DAC.

The amplifier bandwidth is determined by the interaction between the feedback resistor R_FB and the selection of the capacitor in parallel with R_FB. The capacitive feedback value C_FB can be set to one of four values in either the parameter dialog or by using the TIA_SetCapFB() API function. The –3 dB frequency for the amplifier is:

\[
\text{Freq – 3 dB} = 1/(2\pi R_FB C_FB)
\]
Resources
The TIA uses one SC/CT analog block. Typically, the Vref input is routed from a voltage reference, a VDAC output, or an externally supplied reference on a GPIO.

API Memory Usage
The component memory usage varies significantly, depending on the compiler, device, number of APIs used and component configuration. The following table provides the memory usage for all APIs available in the given component configuration.

The measurements have been done with the associated compiler configured in Release mode with optimization set for Size. For a specific design the map file generated by the compiler can be analyzed to determine the memory usage.
