

The following document contains information on Cypress products. Although the document is marked with the name "Spansion" and "Fujitsu", the company that originally developed the specification, Cypress will continue to offer these products to new and existing customers.

Continuity of Specifications

There is no change to this document as a result of offering the device as a Cypress product. Any changes that have been made are the result of normal document improvements and are noted in the document history page, where supported. Future revisions will occur when appropriate, and changes will be noted in a document history page.

Continuity of Ordering Part Numbers

Cypress continues to support existing part numbers. To order these products, please use only the Ordering Part Numbers listed in this document.

For More Information

Please contact your local sales office for additional information about Cypress products and solutions.

About Cypress

Cypress (NASDAQ: CY) delivers high-performance, high-quality solutions at the heart of today's most advanced embedded systems, from automotive, industrial and networking platforms to highly interactive consumer and mobile devices. With a broad, differentiated product portfolio that includes NOR flash memories, F-RAM™ and SRAM, Traveo™ microcontrollers, the industry's only PSoC® programmable system-on-chip solutions, analog and PMIC Power Management ICs, CapSense® capacitive touch-sensing controllers, and Wireless BLE Bluetooth® Low-Energy and USB connectivity solutions, Cypress is committed to providing its customers worldwide with consistent innovation, best-in-class support and exceptional system value.

Errata

This errata sheet is for MB91640A/645A Series Hardware Manual Rev. 1 (CM71-10154-1E).

FR80
 32-BIT MICROCONTROLLER
 MB91640A/645A Series
 HARDWARE MANUAL

2011.12.16
 : Corrected part

| 2011/6/29 | 7 | 1.2 | Table 1.2-1 was changed as indicated by the shading below. (Error) Built-in RAM capacity (Correct) Built-in RAM capacity(Instruction execution enabled) [mcu doc1068] | | | | | | | | | | |
| 2011/6/29 | 9 | 1.3 | Figure 1.3-1 was changed as indicated by the shading below. (Error) RAM (Correct) Built-in RAM (Instruction execution enabled) [mcu doc1068] | | | | | | | | | | |
| 2011/6/29 | 101 | 3.1 | Figure 3.1-1 was changed as indicated by the shading below. (Error) Built-in RAM area (Correct) Built-in RAM area(Instruction execution enabled) [mcu doc1068] | | | | | | | | | | |
| 2009/7/6 | 158 | 4.4.3 | The table of [bit3 to bit0] was corrected as indicated by the shading below. <table border="1" style="margin: 10px auto; border-collapse: collapse;"> <thead> <tr> <th>MOSW3</th> <th>MOSW2</th> <th>MOSW1</th> <th>MOSW0</th> <th>Main Clock (MCLK) Oscillation Stabilization Wait Time</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">$2^8 \times$ Main clock (MCLK) period</td> </tr> </tbody> </table> [mcu doc1002] | MOSW3 | MOSW2 | MOSW1 | MOSW0 | Main Clock (MCLK) Oscillation Stabilization Wait Time | 0 | 1 | 0 | 0 | $2^8 \times$ Main clock (MCLK) period |
| MOSW3 | MOSW2 | MOSW1 | MOSW0 | Main Clock (MCLK) Oscillation Stabilization Wait Time | | | | | | | | | |
| 0 | 1 | 0 | 0 | $2^8 \times$ Main clock (MCLK) period | | | | | | | | | |
| 2010/3/23 | 132 | 3.11.4 | The following description was added to the end of the page. If an interrupt is received while executing an instruction to set I flag to “0”, there is a delay for 1 cycle from execution of an instruction for I flag and ILM to change. Therefore, I flag becomes “0” although processing moves to the interrupt processing routine. At this time, if multiple interrupts are generated, I flag can not receive any interrupt because it is “0”, and processing of multiple interrupts is not performed. I flag itself is updated when executing an instruction. Therefore, a value of I flag after update is saved to the stack, and when the value of the stack is returned, the value of I flag after update is reflected to PS register. To receive a new interrupt within the interrupt routine, it is required to set software to make I flag to “1” at the beginning of the interrupt routine. [mcu doc1056] | | | | | | | | | | |

1. DMA transfer operation (through scan conversion interrupt requests)

2. DMA retransfer operation

< Attached document 2 >

Notes on UART Mode

The notes for when you use the UART mode are shown below.

- FIFO cannot be used for requesting DMA transfer with a channel with FIFO. Please set as FIFO operation disable.
- To request a DMA transfer request, set the block size of DMA to one time.

Notes on CSIO Mode

The notes for when you use the CSIO mode are shown below.

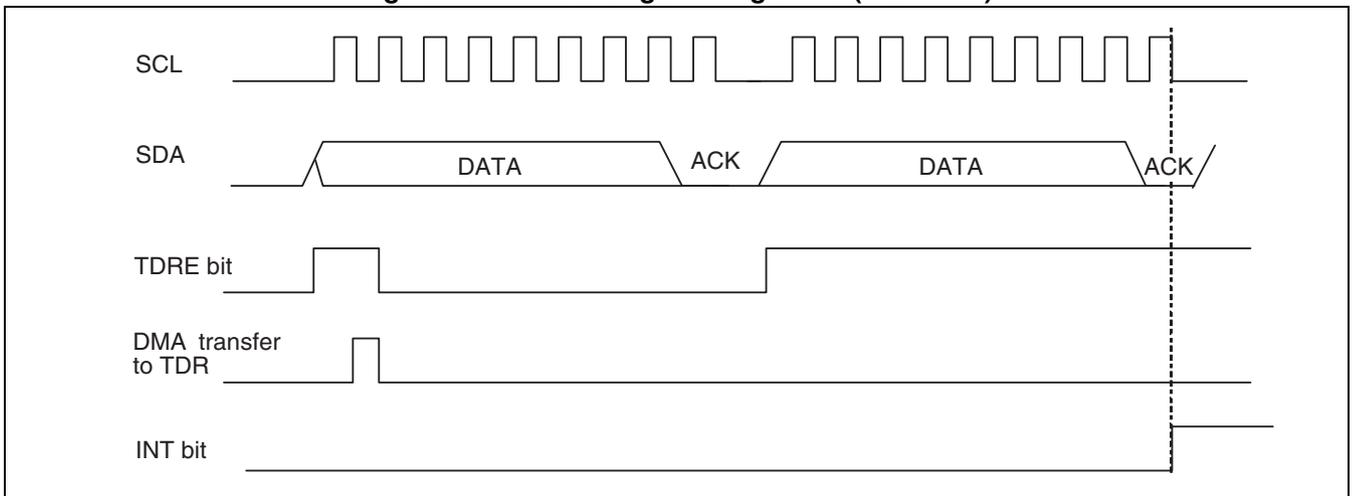

- FIFO cannot be used for requesting DMA transfer with a channel with FIFO. Please set as FIFO operation disable.
- To request a DMA transfer request, set the block size of DMA to one time.
- When master reception and slave reception are selected, it is required to use two channels for DMA; one is used for DMA transfer to receive data and the other one is used for DMA transfer to send dummy data.

Notes on I²C Mode

The notes for when you use the I²C mode are shown below.

- FIFO cannot be used for requesting DMA transfer with a channel with FIFO. Please set as FIFO operation disable.
- To request a DMA transfer request, set the block size of DMA to one time.
- When master reception and slave reception are selected, it is required to use two channels for DMA; one is used for DMA transfer to receive data and the other one is used for DMA transfer to send dummy data.
- In I²C mode, if there is no valid data in transmission register (TDR), and transmission data empty flag bit (TDRE) is "1", the interrupt flag (INT) becomes "1" as shown in Figure 1 when the data on I²C bus for 9 bits (WSEL=0) or for 8 bits (WSEL=1) is transmitted. When the interrupt flag (INT) becomes "1" during DMA transfer, DMA transfer cannot be continued unless clearing the bit to "0" by software. (Common to master transmission, slave transmission, mater reception, and slave reception.)

Figure 1 INT Bit Change Timing of I²C (WSEL= 0)

To perform DMA transfer in I²C mode, since the specification is as shown above, such operations listed below are required for performing DMA transfer to TDR before the interrupt flag (INT) becomes "1". Below operations are possible to perform to prioritize DMA transfer of I²C.

- Use DMA which has a higher priority (channel number is small). It is enabled to use by fixing the priority setting bit (AT=0).
- Set the value of DMA-halt by interrupt level bit as small as possible (LVL4-LVL0 bit in DILVR register).

< Attached document 4-2 >

- In case of writing the transmission data to transmission data register (TDR) by DMA transfer after transmission data empty flag (SSR:TDRE) becomes "1", or writing the data by software confirming the transmission data empty flag (SSR:TDRE), transmission data empty flag (SSR:TDRE) may not become "0". Therefore, the transmission data should be written before SCL in ACK field falls. There are no restrictions on writing the transmission data by software after the interrupt flag (IBCR:INT) becomes "1".

When performing DMA transfer or sending the data by software confirming the transmission data empty flag (SSR:TDRE), please follow below procedures if the data cannot be written before SCL in ACK field falls.

- Setting

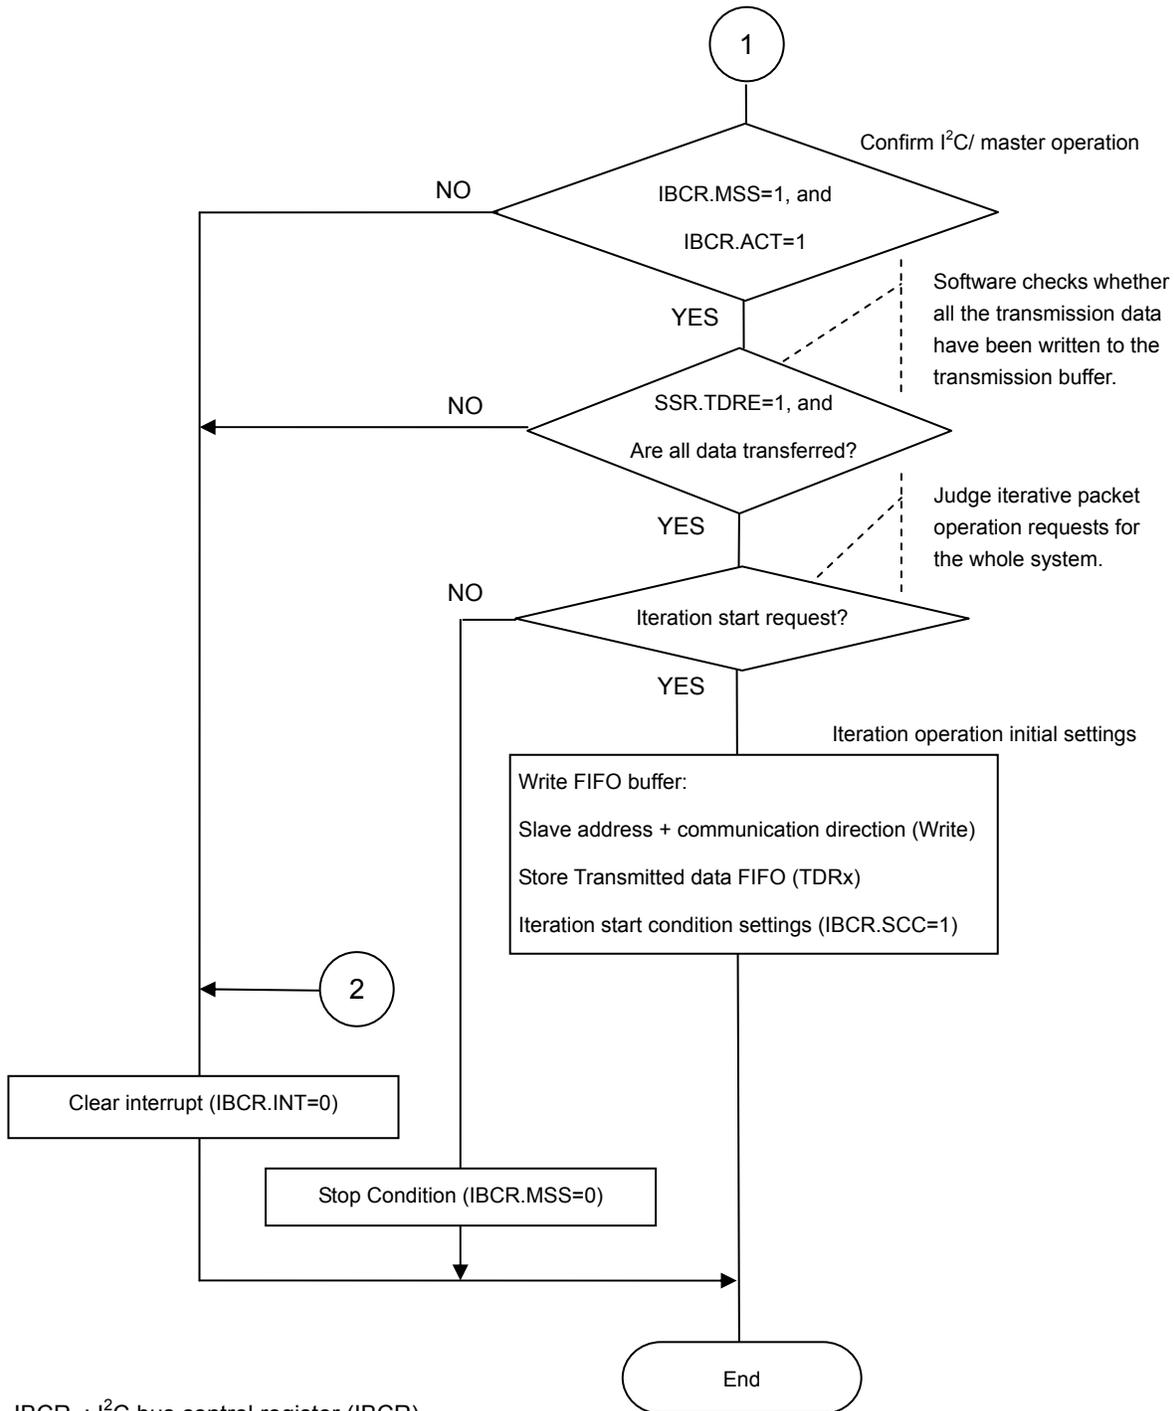

Set the timing of interrupt flag (IBCR:INT) becoming "1" to the 8th bit (WSEL=1).

- Procedures

To transmit or receive data by master, the following procedures are required. To transmit or receive data by slave, it is not required to perform the following.

1. Write the first byte (slave address) to the transmission data register by software.
2. Set to 8-bit for wait selection (IBCR:WSEL="1" write) at the same time that master is started (IBCR:MSS="1" write).
3. After sending the first byte, the interrupt flag (IBCR:INT) becomes "1". Write the second byte to transmission data register (TDR) by software after confirming ACK response (IBSR:RACK="0"). Set the DMAC, and activate DMA transfer, then write "0" to interrupt flag (IBCR:INT).
4. After transmission and reception are completed, terminate the master (IBCR:MSS="0" write) or reboot (IBCR:SCC="1" write).

< Attached document 5-2 > Master Transmission Interrupt Process

IBCR : I²C bus control register (IBCR)
 TDR : Transmitted data register (TDR)
 SSR : Serial status register (SSR)

* For actual error handling, please judge each status error flag and handle each error by considering your systems.

31.6.7 Continuous Mode Operation

This section explains the continuous mode operation.

■ Continuous mode

In this mode, if the continuous mode commands are written, the unlock cycle in usual command sequence is unnecessary. Therefore, it is possible to write data by the bus operation of two times instead of the bus operation of four times in the continuous mode (do not write the erase command.). Moreover, the read is usually operation and do not write the commands other than the continuous write command/the continuous mode reset command during the continuous mode.

To end this mode, write the continuous mode reset command. Therefore, it is not possible to terminate the continuous mode even when the reset command ($F0_H$) is written in this mode.

When the continuous mode reset command is written, it returns to usual read mode (For details, see Figure 31.6-3.).

■ Continuous write mode

It is possible to write data by the bus operation of two times in the continuous mode. The automatic write algorithm is started by writing the write setup command ($A0_H$) and the write data cycle (PA/PD) in the continuous mode. This command has the same function as usual write operation except data writing by the bus operation of two times (For details, see Figure 31.6-3.).

Figure 31.6-3 shows an example of the flash memory continuous write operation.

Figure 31.6-3 Continuous Write Procedure Example
