Features

- Selectable 8-, 10-, or 12-bit resolution
- Interleaved or channel-sequential averaging in hardware
- Up to 16-bit resolution with averaging
- Aggregate sample rate up to 1 Msps
- Single-ended and Differential input modes
- Optional 2\textsuperscript{nd} order switched-cap filter on channel 0
- Scheduler optimizes settling time and clock to fit scan rate
- Scan up to sixteen analog signals automatically

General Description

The Scanning SAR ADC component gives configuration-, schematic-, and firmware-level support for the version of the SAR (‘Successive Approximation Register’) ADC present on some members of the PSoC family. Up to sixteen analog channels (from sources dependent on the specific device) can be automatically scanned, either on demand or continuously, with the results placed in individual result registers. One of the channels may be routed through a 2\textsuperscript{nd} order switched-cap filter. The scan scheduler adjusts internal sampling behavior and clock to accommodate specific settling time and overall scan rate requirements. Averaging can be applied to any channel in a scan.

When to Use a Scanning SAR ADC

The Scanning SAR ADC is the component used to access the ADC functionality in members of the ‘PSoC Analog Coprocessor’ family. It is flexible and versatile in both high sample rate continuous-sampling applications (timed entirely in hardware), and lower-rate ad-hoc triggered scan applications.

The offset and span of the ADC depend on the parameters configured for the component. Regardless of these settings, the analog signals connected to the PSoC’s pins must be between V\textsubscript{SSA} and V\textsubscript{DDA}. For some settings, ‘rail-to-rail’ conversion is possible.
Input/Output Connections

This section describes the various input and output connections for the Scanning SAR ADC that may appear as terminals on the component symbol. An asterisk (*) after the terminal name indicates that the terminal may not be present on the symbol under certain conditions.

Note Throughout this document when signal connections are abbreviated, 's/e' means single-ended, 'diff' means differential.

Note During the sampling time for a given channel, its +Input, -Input, and/or vneg input signals connect directly to the input capacitor of the ADC core, and must charge that capacitor up before the actual conversion. An input settling time value can be entered into each channel's parameter selections to allow for that channel's source impedance.

+Input – Analog

This input (not marked; it is always the upper terminal of a differential input pair on the symbol) is the ‘positive’ (also called non-inverting) analog signal input to the ADC. There are always the same number of ‘positive’ analog signal input terminals as there are channels selected, whether they are specified as differential or single-ended.

–Input – Analog *

This input (not marked; it is always the lower terminal of a differential input pair on the symbol) is the ‘negative’ (also called inverting) analog signal input to the ADC. It is only present for channels that have been declared as differential. On all channels declared as single-ended channels, the inverting input of the ADC is connected instead to the Vneg signal, described below. There are always the same number of ‘negative’ analog signal input terminals as there are differential channels selected.

vneg – Analog Input*

This is a common negative input reference. This terminal is present only if one or more analog channels are declared as a single-ended input and the Vneg for S/E parameter is set to External.
soc – Digital Input *

This terminal is present if the “Use signal on soc terminal” box is checked. See the Sample Mode section for a description of how the soc terminal is used by the component.

PSoC Creator components can be stopped and started with firmware API calls. To allow for circuit stabilization, the first soc rising edge should be generated at least 10 us after calling the ADC_Start() function.

vagnd – Analog Input *

This terminal appears on the symbol if the filter function available on channel 0 is enabled. It is intended to be connected to the locally-generated voltage used for referencing analog signals (sometimes called Analog ground) and is connected by the user.

vref – Analog Input *

This terminal appears on the symbol if the Vref parameter is set to Symbol terminal voltage.

aclk – Clock Input *

This terminal allows a PSoC clock to be connected to the component. This mode is used when it is important that the clock used by the ADC is identical to that used by another component on the schematic.

You can add this optional terminal if you check the ‘Show analog clock (aclk) terminal’ selection, otherwise, the terminal is hidden. Without this terminal, the component will auto-select the ADC clock frequency, which may allow closer matching of user-specified sample rate.

sdone – Digital Output

This signal goes high for two ADC clock cycles to indicate that the ADC has sampled the current input channel. Internally, this signal is used to advance the signal multiplexer onto the next channel.

eos – Digital Output

A rising edge on the end of scan (eos) output means that the current scan is complete. At this moment, conversion result registers contain valid sample data for all enabled channels. Internally, it is used to provide an interrupt.
Component Parameters

This section covers the various parameters that can be altered or inspected through the setup customizer of the component, grouped within a series of tabs. To explore this, drag a Scanning SAR ADC onto your design and double click it to open the Configure dialog. For any selectable parameter, the option shown here in **bold** is the default.

Config Tab – Scan Sub-Tab
Timing

Free-run scan rate (SPS)
This is the fundamental parameter for the Scanning SAR ADC; the desired rate at which completed scans should be executed when the component is running in Continuous mode. It is the rate at which each signal included in the scan is sampled. The Scanning SAR ADC component customizer has a schedule calculator that works to get this sample rate as close as possible to the value that is entered. It does this by intelligent selection of ADC clock frequency (when an internal clock source is selected) and channel sampling times, taking all the other user-entered requirements into account.

When selected, the ADC clock rate is automatically calculated based on the number of channels, averaging, resolution, and acquisition time parameters to meet the entered sample rate.

Achieved (display only)
This field displays the currently-achieved scan rate that the component will implement in a running system. The scheduler adjusts everything available to get as close as it can to the desired scan rate, but this is not always possible.

Available rates (display only)
This field shows the approximate minimum to maximum range of scan rates that can currently be attained with the setup as defined. This field will change based on channel parameters, such as acquisition time and whether averaging is used. If the desired free-running rate is less than the minimum rate shown here, the solution is to set up a TC/PWM timer on the schematic and use it to trigger the ADC periodically (in single shot triggered mode).

ADC clock rate (display only)
This field displays the currently-selected actual ADC clock frequency. It is an integer divide from the PSoC’s main high frequency clock.

Scan Duration (display only)
This field gives the duration of the achieved overall scan, in ns.

Sample Mode
The Scanning SAR ADC can operate in one of two modes:

<table>
<thead>
<tr>
<th>Sample mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Continuous</td>
<td>Once started, Scanning SAR ADC runs continuously until stopped</td>
</tr>
<tr>
<td>Single shot</td>
<td>Scanning SAR ADC takes one scan per valid firmware or hardware trigger</td>
</tr>
</tbody>
</table>
**Use soc terminal**

The Scanning SAR ADC can always be started and stopped in firmware with the ADC_StartConvert() and ADC_StopConvert() functions.

If this box is checked, hardware triggering via the start-of-conversion (soc) terminal on the component is enabled. The soc terminal is created on the component symbol by checking the “Use signal on soc terminal” on the Scan sub tab.

With this hardware triggering enabled, in single-shot mode a single complete scan of the Scanning SAR ADC is triggered by a positive-going edge applied to the soc terminal. In continuous mode, the ADC takes scans back-to-back if a ‘1’ level is applied to the soc terminal.

Enabling hardware triggering does *not* suppress the firmware triggering function. Exercise caution in interpreting data sets resulting from a combination of both forms of triggering, since the trigger source is not reflected in the output data.

**Input range**

**Vref select**

The Vref parameter selects the reference voltage source that is used for the ADC core, and optionally enables a numeric value to be given to it if the customizer does not know it.

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design-wide reference</td>
<td>This is the reference voltage that is assigned by Creator for multiple use in the design.</td>
</tr>
<tr>
<td><strong>System Bandgap</strong></td>
<td>Dedicated internal connection to the main 1.2 V reference</td>
</tr>
<tr>
<td>Symbol terminal</td>
<td>The voltage fed to this terminal on the symbol is used as the reference</td>
</tr>
<tr>
<td>External device pin</td>
<td>Depending on the device part number, this pin is a dedicated or shared pin, used both for the Vref off-chip bypass capacitor and for the injection of a reference external to the chip.</td>
</tr>
<tr>
<td>Vdda/2</td>
<td>An internal resistor divider produces Vdda/2 as a reference</td>
</tr>
<tr>
<td>Vdda</td>
<td>Uses the internal Vdda. An off-chip bypass capacitor has no effect in this mode.</td>
</tr>
</tbody>
</table>

The internal Vref startup time varies with different bypass capacitors. This table lists two common values for the bypass capacitor and its startup time specification.

<table>
<thead>
<tr>
<th>Internal Vref Startup Time</th>
<th>Maximum Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Startup time for reference with external capacitor (1 µF)</td>
<td>2 ms</td>
</tr>
<tr>
<td>Startup time for reference with external capacitor (100 nF)</td>
<td>200 µs</td>
</tr>
</tbody>
</table>

**PRELIMINARY**
**Vref value (user entry or parameter display)**

To the right of the Vref select pull-down, this parameter either displays the reference voltage value that is being used for the SAR ADC (if this is ‘known’ to PSoC Creator) or enables the entry of a value for display purposes, if only the user knows this value.

**Vref bypass**

Checking this box indicates to the component customizer that you have attached an off-chip bypass capacitor to the specific device pin set aside for this. It permits the component to select higher ADC clock rates and therefore significantly higher overall scan rates.

The use of an off-chip reference bypass capacitor (33 nF or greater, X7R dielectric or better) is recommended in all systems. It should only be omitted when there is really no room for it on the build. When omitted, the maximum aggregate sample rate is reduced by at least a factor of eighteen, and conversions are more prone to digital noise on the circuit board.

**Vneg for S/E**

This parameter selects where the negative input to the SAR ADC is connected if any channels are configured for single-ended operation.

<table>
<thead>
<tr>
<th>Negative input</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vssa</td>
<td>Input range is 0.0 to Vref, effective resolution will be one bit less than selected in the customizer.</td>
</tr>
<tr>
<td>Vref</td>
<td>Input range is 0.0 to Vref*2.</td>
</tr>
<tr>
<td>External</td>
<td>This mode is configured for “quasi-differential” inputs. Multiple channels share one common –ve (inverting) connection. This is often used for common-mode rejection of ground noise in multi-channel systems.</td>
</tr>
</tbody>
</table>

**12-bit code range (display only)**

This field displays what code ranges will be returned by the SAR ADC. The values displayed are truncated at 12-bits. However, the results returned will be sign extended to the 16 or 32 bit format depending on which GetResult function is used.

**Volt range (display only)**

This field displays the voltage range of the SAR ADC using the selected Vref. For single ended channels the selection of Vneg is also used to determine the range.
**Result Data Format**

**Differential (Diff.) result format**

This parameter determines whether or not the result from a differential measurement is **Signed** or Unsigned. This is a global setting for all differential channels. Results are always right-justified.

**S/E result format**

This parameter determines whether or not the result from a single-ended measurement is Signed or **Unsigned**. This is a global setting for all single-ended channels. Results are always right-justified.

The following table shows how these parameters affect conversion of the input voltage to the 12 bit digital sample value.

<table>
<thead>
<tr>
<th>s/e or diff</th>
<th>Signed / Unsigned</th>
<th>Single-ended negative input</th>
<th>-Input</th>
<th>+Input</th>

<td>N/A</td>
<td>Vx</td>
<td>Vx+Vref Vx Vx-Vref</td>
<td>0x07FF 0x0000 0xF800</td>
</tr>
</tbody>
</table>

For single-ended conversions with the **Vneg for S/E** parameter set to **Vssa**, the usable conversion is effectively 11-bit. Noise or offset on the **+Input** terminal with a level slightly below
Vss produces a result that appears more positive than full scale. This can cause severe system problems, so this mode should be used with caution.

**Samples averaged**

This parameter sets the averaging rate for any channel with the averaging option enabled. This is a global setting for all channels that have averaging enabled. Default value is 2.

Note that the interleaved averaging option does not support result realignment, it is a simple accumulation. For average counts of greater than 16, it is possible (under large-signal conditions) for the result register to overflow and wrap round. This error is not detected by the hardware. Only use more than 16 sample averaging in interleaved mode if you are satisfied that this wrap-round will not occur on your particular signals.

**Averaging mode**

This parameter sets how the hardware averaging mode operates. If Sequential, Sum is selected, each ADC conversion result is added to a running sum. It’s then shifted so that it fits into a 16-bit result word. If the Sequential, Fixed mode is selected, accumulated result is shifted back into a 12-bit result.

In either sequential mode, the scan pauses on the channel being averaged and all the samples for the average are taken before moving onto the next channel in the scan. This can reduce the maximum available scan rate substantially when any channel in the scan is averaged in this way. For this reason, the Interleaved, Sum mode is also available. In Interleaved mode, only one conversion is taken on each channel before moving on, but channels that have averaging enabled get the preset number of samples accumulated in their result register.

In **Interleaved, Sum mode** the overall scan rate is not reduced. This means that channels not requiring averaging can still be sampled at the original scan rate. An end of scan interrupt is still produced at the end of every scan; channels that utilize interleaved averaging are not marked as ‘valid’ until the correct number of scans have been taken.

If every channel is set to use averaging and the mode is set to Interleaved, Sum then the rate of end-of-scan interrupts is significantly reduced.

**Alternate resolution**

This parameter sets the alternate ADC resolution to either 8 or 10 bits. This alternate resolution can be selected for any channel instead of the native 12-bit. Note that averaging always uses 12-bit resolution, ignoring this parameter. The component will issue a warning if the two modes are set together on any channel.
Interrupt Limits

Compare mode

The Scanning SAR ADC supports range detection to allow for the automatic detection of sample values compared to two programmable thresholds without CPU involvement. A range detect is defined by two global thresholds and a condition.

This parameter sets the condition under which a limit condition will occur and trigger a maskable range detect interrupt.

<table>
<thead>
<tr>
<th>Compare Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result &lt; Low</td>
<td>Below range</td>
</tr>
<tr>
<td>Low &lt;= Result &lt; High</td>
<td>Inside range</td>
</tr>
<tr>
<td>High &lt;= Result</td>
<td>Above range</td>
</tr>
<tr>
<td>(Result &lt; Low) or (High &lt;= Result)</td>
<td>Outside range</td>
</tr>
</tbody>
</table>

Low (hex)

This parameter sets the low threshold in hex for a limit compare. Default value is 0x0200. For Signed modes, the SAR results are two’s-complement.

High (hex)

This parameter sets the high threshold in hex for a limit compare. Default value is 0x0E00.

A range detect is done after averaging, alignment, and sign extension (if applicable). In other words, the thresholds values must have the same data format as the final 16-bit conversion result.

Equivalent input voltages:

Directly beneath the low and high limit entry fields, the corresponding voltage values are displayed for individual and averaged differential and single-ended measurements.

Channels

Number of channels

This parameter selects how many input signal channels are scanned. By default, there are 2 channels. The maximum number of channels is either 8 or 16 depending on the device. It depends also on mode (differential or single-ended) and available resources outside of the SAR. The minimum number of channels is always 1.
A set of parameters is available for each entry. The actual number of entries depends on the **Number of channels** parameter. The symbol shows as many channels as are selected by the **Number of channels** parameter even if the channel is not enabled.

**Ch.**

Shows the number of the channel, starting from 0. The number of entries here is determined by the Number of Channels parameter.

**En**

If checked, the channel is enabled in the scan. If unchecked, no time is consumed and the scan jumps immediately to the next enabled channel in the scan list.

**Resolution**

This parameter selects either 12 bits or the alternative (ALT) resolution setting.

**Input mode**

For any channel, this parameter selects the input mode to the ADC as either **Differential** or Single ended. In addition, channel 0 can be configured to take its signal through a dedicated 2\textsuperscript{nd} order filter whose frequency response parameters can be set over a wide range. The filter has a single-ended input, and the output of the filter is measured with respect to the voltage applied to the **vagnd** terminal. See the Switched-capacitor filter section for more information about the filter.

**Avg**

This option selects whether or not the channel is averaged. When selected and a sequential averaging mode is selected, the SAR sequencer stays on the channel and takes N readings, then adds the results together. The number of samples taken is determined by the **Samples averaged** parameter. Averaging is available only for the maximum **Resolution** selected in a particular channel. Select ALT resolution for all channels to allow averaging on fewer than 12 bits resolution. Averaging is always right-aligned.

**Minimum acq. time (ns)**

The user can enter a minimum acquisition time (in ns) that the input sampling process will dwell on this channel before actually making the conversion. The field is editable but is pre-populated with the shortest value currently possible with the system clock parameters.

**Achieved acq. time (ns)**

This display field shows the acquisition time (in ns) that the scheduler has selected. It is always equal to or higher (longer duration) than the user-requested value.
**Limit interrupt**

This option allows you to enable an interrupt if any of the channels trigger the limit criteria set by the **Low** or **High** thresholds and the **Compare mode** parameter. This interrupt triggers at the end of the current scan.

**Sat. interrupt**

This option allows you to enable an interrupt from any channel where the result is saturated at either the lowest or the highest value for the given resolution and format. This interrupt triggers immediately.
Config Tab – Filter Sub-Tab

This tab sets up the behavior of the 2\textsuperscript{nd} order switched-capacitor filter that can optionally be connected to channel 0 (the first channel in the scan).

Filter type

The filter implements four different response types: lowpass, highpass, bandpass and notch (also called bandstop). The lowpass and highpass filters have a programmable stopband notch frequency. All the filter types are calculated with the so-called maximally-flat response form, of which the well-known Butterworth filter is a simple example.

All filters have a peak passband gain of unity, i.e. 0 dB.
Frequency entry fields
Underneath the pull-down for filter type are two frequency entry fields, whose titles and purpose change with the filter types.

For the lowpass and highpass filter, the user specifies the desired frequency of the -3 dB point, and also the desired frequency of the 'notch' in the stopband. That can be useful for achieving additional attenuation at a specific frequency.

For the bandpass filter, the user enters the desired frequencies for the lower and upper -3 dB response points. This is more direct than entering a center frequency and a bandwidth, which would not make clear where those -3 dB frequencies actually are.

For the Notch filter, the user specifies the frequency of the notch, and a -3 dB shoulder. The -3 dB shoulder can be below or above the notch frequency.

The customizer will issue appropriate errors if the user enters frequency combinations that are not meaningful for the type of filter. Each filter type has its own stored frequency settings, so the frequencies in the user entry boxes may change when the filter type selection is changed.

In this version of the Scanning SAR ADC there is no API function for changing the filter behavior. This is due to the close integration of the filter clocking requirements with the acquisition timing needs of the ADC core.

**Note** The filter has a single-ended input, which is referred to an 'analog ground' voltage which is applied to the \textit{vagnd} terminal, which is always present on the schematic if the filter has been selected. The optimum value for this voltage is half the analog supply voltage. This voltage is typically available through a reference voltage component on the PSoC Creator schematic. A suitable voltage must be connected to this terminal if it is present.

**Sample Frequency (kHz) (display only)**
This display field shows the selected sample frequency of the filter. The maximum sample frequency is 1MHz. The minimum sample frequency is set by the filter requirements. The minimum sample frequency will be at least the Nyquist Rate. The filter sample frequency will also be an integer multiple of the ADC clock rate to ensure proper alignment between the ADC and the filter.
Common Tab

Show analog clock (aclk) terminal
If this box is checked, the external analog clock (aclk) terminal will appear on the symbol.

Application Programming Interface

Application Programming Interface (API) routines allow you to configure the component using software. This table lists and describes the interface to each function. The following sections cover each function in more detail.

By default, PSoC Creator assigns the instance name "ADC_1" to the first instance of a component in a given design. You can rename it to any unique value that follows the syntactic rules for identifiers. The instance name becomes the prefix of every global function name, variable, and constant symbol. For readability, the instance name used in the following table is "ADC".

Note Do not use the ADC_Stop() API to halt conversions. Instead use the ADC_StopConvert() API. If you use the ADC_Stop() API to halt conversions then later use the ADC_Start() and ADC_StartConvert() APIs to resume conversions, the first channel of the scan may be corrupt. The StopConvert() API will enable the Scanning SAR ADC to complete the current scan of channels. After the channel scan is complete, the Scanning SAR ADC will stop all conversions, which can be detected by the use of an ISR or the ADC_IsEndConversion() flag.
Note that no explicit functions for saving and loading the hardware state are provided. Everything needed to set up the SAR hardware is provided in the main API functions.

Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

</table>
Function | Description
---|---
ADC_Wake() | Restores the component enable state and configuration registers.

void ADC_Start(void)

Description: Performs all required initialization for this component and enables the power. The power will be set to the appropriate power based on the clock frequency.

Parameters: None

Return Value: None

Side Effects: None

void ADC_StartEx(cyisaddress address)

Description: This function starts the ADC and sets the Interrupt Service Routine to the provided address using the ADC_IRQ_StartEx() function. Refer to the Interrupt component datasheet for more information on the ADC_IRQ_StartEx() function.

Parameters: address: This is the address of a user defined function for the ISR.

Return Value: None

Side Effects: None

void ADC_Stop(void)

Description: This function stops ADC conversions and puts the ADC into its lowest power mode.

Parameters: None

Return Value: None

Side Effects: Don’t use the Stop() API to halt conversions. Instead use the StopConvert() API. If you use the Stop() API to halt conversions then later use the ADC_Start() and ADC_StartConvert() APIs to resume conversions, the first channel of the scan may be corrupt. The StopConvert() API will enable the Scanning SAR ADC to complete the current scan of channels. After the channel scan is complete, the Scanning SAR ADC will stop all conversions, which can be detected by the use of an ISR or the ADC_IsEndConversion() flag.
void ADC_StartConvert(void)  
**Description:** In continuous mode, this API starts the conversion process and it runs continuously. In Single Shot mode, the function triggers a single scan and every scan requires a call of this function. The mode is set with the Sample Mode parameter in the customizer. The customizer setting can be overridden at run time with the ADC_SetConvertMode() function.

**Parameters:** None  
**Return Value:** None  
**Side Effects:** None

void ADC_StopConvert(void)  
**Description:** Forces the ADC to stop conversions. If a conversion is currently executing, that conversion will complete, but no further conversions will occur.

**Parameters:** None  
**Return Value:** None  
**Side Effects:** None

void ADC_SetConvertMode(uint32 mode)  
**Description:** Sets the conversion mode to either Single-Shot or continuous. This function overrides the settings applied in the customizer. Changing configurations will restore the values set in the customizer.

**Parameters:** mode: Sets the conversion mode. See table below for details.

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADC_SINGLE_SHOT</td>
<td>Calling the ADC_StartConvert() function after setting mode this will trigger a single scan. Sets the SOC signal to be edge sensitive, each edge will trigger a single scan.</td>
</tr>
<tr>
<td>ADC_CONTINUOUS</td>
<td>Calling the ADC_StartConvert() function after setting this mode trigger continuous scanning. This mode sets the SOC signal to be level sensitive. The ADC will continuously scan while soc is active.</td>
</tr>
</tbody>
</table>

**Return Value:** None  
**Side Effects:** None
void ADC_IRQ_Enable(void)

Description: Enables interrupts to occur at the end of a conversion. Global interrupts must also be enabled for the ADC interrupts to occur.

Parameters: None

Return Value: None

Side Effects: None

void ADC_IRQ_Disable(void)

Description: Disables end of conversion interrupts.

Parameters: None

Return Value: None

Side Effects: None

void ADC_SetEosMask(uint32 mask)

Description: Sets or clears the End of Scan (EOS) interrupt mask.

Parameters: mask: 1 to set the mask, 0 to clear the mask.

Return Value: None

Side Effects: All other bits in the INTR register are cleared by this function.

void ADC_SetChanMask(uint32 mask)

Description: Sets enable/disable mask for all channels.

Parameters: mask: 1 to set the mask, 0 to clear the mask.

Return Value: None

Side Effects: Enabling or disabling a channel disrupts the scheduled timing and changes the sample rate.
uint32 ADC_IsEndConversion(uint32 retMode)

**Description:** Immediately returns the status of the conversion or does not return (blocking) until the conversion completes, depending on the retMode parameter.

**Parameters:** 
retMode: Check conversion return mode. See the following table for options.

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADC_RETURN_STATUS</td>
<td>Immediately returns the conversion status for sequential channels. If the value returned is zero, the conversion is not complete, and this function should be retried until a nonzero result is returned.</td>
</tr>
<tr>
<td>ADC_WAIT_FOR_RESULT</td>
<td>Does not return a result until the ADC conversion of all sequential channels is complete.</td>
</tr>
<tr>
<td>ADC_RETURN_STATUS_INJ</td>
<td>Immediately returns the conversion status for the injection channel. If the value returned is zero, the conversion is not complete, and this function should be retried until a nonzero result is returned.</td>
</tr>
<tr>
<td>ADC_WAIT_FOR_RESULT_INJ</td>
<td>Does not return a result until the ADC completes injection channel conversion.</td>
</tr>
</tbody>
</table>

**Return Value:** uint8: If a nonzero value is returned, the last conversion is complete. If the returned value is zero, the ADC is still calculating the last result.

**Side Effects:** This function reads the end of conversion status, and clears it afterward.

int16 ADC_GetResult16(uint32 chan)

**Description:** Gets the data available in the channel result data register.

**Parameters:** 
chan: The ADC channel to read the result from. The first channel is 0 and the injection channel if enabled is the number of valid channels.

**Return Value:** Returns converted data as a signed 16-bit integer

**Side Effects:** None.

int16 ADC_GetResult32(uint32 chan)

**Description:** Gets the data available in the channel result data register.

**Parameters:** 
chan: The ADC channel to read the result from. The first channel is 0 and the injection channel if enabled is the number of valid channels.

**Return Value:** Returns converted data as a signed 32-bit integer

**Side Effects:** None.
void ADC_SetLowLimit(uint32 lowLimit)

Description: Sets the low limit parameter for a limit condition.
Parameters: lowLimit: The low limit for a limit condition.
Return Value: None
Side Effects: None

void ADC_SetHighLimit(uint32 highLimit)

Description: Sets the high limit parameter for a limit condition.
Parameters: highLimit: The high limit for a limit condition.
Return Value: None
Side Effects: None

void ADC_SetLimitMask(uint32 mask)

Description: Sets the channel limit condition mask.
Parameters: mask: Sets which channels that may cause a limit condition interrupt. Setting bits for channels that do not exist will have no effect. For example, if only 6 channels were enabled, setting a mask of 0x0103 would only enable the last two channels (0 and 1).
Return Value: None
Side Effects: None

void ADC_SetSatMask(uint32 mask)

Description: Sets the channel saturation event mask.
Parameters: mask: Sets which channels that may cause a saturation event interrupt. Setting bits for channels that do not exist will have no effect. For example, if only 8 channels were enabled, setting a mask of 0x01C0 would only enable two channels (6 and 7).
Return Value: None
Side Effects: None
void ADC_SetOffset(uint32 chan, int16 offset)

Description: Sets the ADC offset that is used by the functions ADC_CountsTo_uVolts, ADC_CountsTo_mVolts and ADC_CountsTo_Volts to subtract the offset from the given reading before calculating the voltage conversion.

Parameters: chan: ADC channel number.

offset: This value is a measured value when the inputs are shorted or connected to the same input voltage.

Return Value: None

Side Effects: None.

void ADC_SetGain(uint32 chan, int32 adcGain)

Description: Sets the ADC gain in counts per 10 volt for the voltage conversion functions below. This value is set by default by the reference and input range settings. It should only be used to further calibrate the ADC with a known input or if an external reference is used. Affects the ADC_CountsTo_uVolts, ADC_CountsTo_mVolts and ADC_CountsTo_Volts functions by supplying the correct conversion between ADC counts and voltage.

Parameters: chan: ADC channel number.

adcGain: ADC gain in counts per 10 volt.

Return Value: None

Side Effects: None.

float32 ADC_CountsTo_Volts(uint32 chan, int16 adcCounts)

Description: Converts the ADC output to Volts as a floating point number. For example, if the ADC measured 0.534 volts, the return value would be 0.534. The calculation of voltage depends on the value of the voltage reference. When the Vref is based on Vdda, the value used for Vdda is set for the project in the System tab of the DWR.

Parameters: chan: ADC channel number.

adcCounts: Result from the ADC conversion

Return Value: Result in Volts

Side Effects: None
int16 ADC_CountsTo_mVolts(uint32 chan, int16 adcCounts)

Description: Converts the ADC output to millivolts as a 16-bit integer. For example, if the ADC measured 0.534 volts, the return value would be 534. The calculation of voltage depends on the value of the voltage reference. When the Vref is based on Vdda, the value used for Vdda is set for the project in the System tab of the DWR.

Parameters: chan: ADC channel number.
adcCounts: Result from the ADC conversion.

Return Value: Result in mV.

Side Effects: None

int32 ADC_CountsTo_uVolts(uint32 chan, int16 adcCounts)

Description: Converts the ADC output to microvolts as a 32-bit integer. For example, if the ADC measured 0.534 volts, the return value would be 534000. The calculation of voltage depends on the value of the voltage reference. When the Vref is based on Vdda, the value used for Vdda is set for the project in the System tab of the DWR.

Parameters: chan: ADC channel number.
adcCounts: Result from the ADC conversion

Return Value: Result in µV

Side Effects: None

void ADC_Sleep(void)

Description: This is the preferred routine to prepare the component for sleep. The ADC_Sleep() routine saves the current component state. Then it calls the ADC_Stop() function and calls ADC_SaveConfig() to save the hardware configuration.

Call the ADC_Sleep() function before calling the CySysPmDeepSleep() or the CySysPmHibernate() function. See the PSoC Creator System Reference Guide for more information about power-management functions.

Parameters: None

Return Value: None

Side Effects: If this function is called twice in the enable state of the component, the disabled state of the component will be stored. So ADC_Enable() and ADC_StartConvert() must be called after ADC_Wakeup() in this case.
void ADC_Wakeup(void)

Description: This is the preferred routine to restore the component to the state when ADC_Sleep() was called. The ADC_Wakeup() function calls the ADC_RestoreConfig() function to restore the configuration. If the component was enabled before the ADC_Sleep() function was called, the ADC_Wakeup() function also re-enables the component.

Parameters: None

Return Value: None

Side Effects: Calling this function without previously calling ADC_Sleep() may lead to unpredictable results.

Global Variables

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADC_initVar</td>
<td>The initVar variable is used to indicate initial configuration of this component. The variable is initialized to zero and set to 1 the first time ADC_Start() is called. This allows for component initialization without reinitialization in all subsequent calls to the ADC_Start() routine. If reinitialization of the component is required, then the ADC_Init() function can be called before the ADC_Start() or ADC_Enable() functions.</td>
</tr>
<tr>
<td>ADC_offset[]</td>
<td>This array calibrates the offset for each channel. It is set to 0 the first time ADC_Start() is called and can be modified using ADC_SetOffset(). The array affects the ADC_CountsTo_Volts(), ADC_CountsTo_mVolts(), and ADC_CountsTo_uVolts() functions by subtracting the given offset.</td>
</tr>
<tr>
<td>ADC_countsPer10Volt[]</td>
<td>This array is used to calibrate the gain for each channel. It is calculated the first time ADC_Start() is called. The value depends on channel resolution and voltage reference. It can be changed using ADC_SetGain(). This array affects the ADC_CountsTo_Volts(), ADC_CountsTo_mVolts(), and ADC_CountsTo_uVolts() functions by supplying the correct conversion between ADC counts and the applied input voltage.</td>
</tr>
</tbody>
</table>

Usable Constants

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADC_TOTAL_CHANNELS_NUM</td>
<td>This constant represents the amount of input channels available for scanning.</td>
</tr>
</tbody>
</table>
Sample Firmware Source Code

PSoC Creator provides numerous example projects that include schematics and example code in the Find Example Project dialog. For component-specific examples, open the dialog from the Component Catalog or an instance of the component in a schematic. For general examples, open the dialog from the Start Page or File menu. As needed, use the Filter Options in the dialog to narrow the list of projects available to select.

Refer to the "Find Example Project" topic in the PSoC Creator Help for more information.

Interrupt Service Routine

The Scanning SAR ADC contains a blank interrupt service routine in the file ADC_INT.c. You can place custom code in the designated areas to perform whatever function is required at the end of a conversion. A copy of the blank interrupt service routine is shown below. Place custom code between the "/* `#START MAIN_ADC_ISR` */ and "/* `#END` */ comments. This ensures that the code will be preserved, when a project is regenerated.

```c
CY_ISR( ADC_ISR )
{
    uint32 intr_status;

    /* Rear interrupt status register */
    intr_status = ADC_1_SAR_INTR_REG;

    /*************************************************************************
    * Custom Code
    * - add user ISR code between the following #START and #END tags
    *************************************************************************/
    /* `#START MAIN_ADC_ISR` */
    /* `#END` */
    /* Clear handled interrupt */
    ADC_1_SAR_INTR_REG = intr_status;
}
```

A second designated area is available to place variable definitions and constant definitions.

```c
/* System variables */

/* `#START ADC_SYS_VAR` */
/* Place user code here. */
/* `#END` */
```

An example of code that uses an interrupt to capture data follows.

```c
#include <project.h>

int16 result = 0;
uint8 dataReady = 0;
void main()
{
    int16 newReading = 0;

    // Interrupt service routine
```
CYGlobalIntEnable; /* Enable Global interrupts */
ADC_1_Start(); /* Initialize ADC */
ADC_1_IRQ_Enable(); /* Enable ADC interrupts */
ADC_1_StartConvert(); /* Start ADC conversions */
for(;;)
{
    if (dataReady != 0)
    {
        dataReady = 0;
        newReading = result;
        /* More user code */
    }
}

Note that you may use an alternative Interrupt service routine, located in your main.c file. In this case use the following template:

Implement interrupt service routine in main.c:

CY_ISR( ADC_ISR_LOC )
{
    uint32 intr_status;
    /* Read interrupt status register */
    intr_status = ADC_1_SAR_INTR_REG;
    /* Place your code here */
    /* Clear handled interrupt */
    ADC_1_SAR_INTR_REG = intr_status;
}

Enable ADC interrupt and set interrupt handler to local routine:

ADC_StartEx(ADC_ISR_LOC);

MISRA Compliance

This section describes the MISRA-C:2004 compliance and deviations for the component. There are two types of deviations defined:

- project deviations – deviations that are applicable for all PSoC Creator components
- specific deviations – deviations that are applicable only for this component

This section provides information on component-specific deviations. Project deviations are described in the MISRA Compliance section of the System Reference Guide along with information on the MISRA compliance verification environment.
The Scanning SAR ADC component has the following specific deviation:

<table>
<thead>
<tr>
<th>MISRA-C: 2004 Rule</th>
<th>Rule Class (Required/Advisory)</th>
<th>Rule Description</th>
<th>Description of Deviation(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8.7</td>
<td>R</td>
<td>Objects shall be defined at block scope if they are only accessed from within a single function.</td>
<td>The object 'ADC_channelsConfig' is always accessed from ADC_Init() function and optionally, depend on component configuration, from ADC_CountsTo_mVolts(), ADC_CountsTo_uVolts, ADC() and ADC_CountsTo_Volts() functions. The intention of this publicly available static variable is to allow more efficient code.</td>
</tr>
<tr>
<td>10.1</td>
<td>R</td>
<td>The value of an expression of integer type shall not be implicitly converted to a different underlying type if: a) it is not a conversion to a wider integer type of the same signedness, or b) the expression is complex, or c) the expression is not constant and is a function argument, or d) the expression is not constant and is a return expression.</td>
<td>The CFG_*HALF_A_CF_VAL constant is cast to an enumerated type limited to a maximum value of 64. In Low-Pass, High-Pass and Notch filters, this value can be up to 127. However, this constant is in place for multi-configuration support, a feature that is not yet enabled.</td>
</tr>
</tbody>
</table>

This component has the following embedded components: Interrupt, Clock and Opamp when the filter is used. Refer to the corresponding component datasheet for information on their MISRA compliance and specific deviations.

## API Memory Usage

The component memory usage varies significantly, depending on the compiler, device, number of APIs used, and component configuration. This table illustrates the memory usage for all APIs available in the default component configuration.

The measurements were done with the associated compiler configured in release mode with optimization set for size. For a specific design analyze the map file generated by the compiler to determine the memory usage.

| Configuration | PSoC Analog Coprocessor | | |
|---------------|-------------------------|------------------|
|               | PSocC Analog Coprocessor | Flash Bytes | SRAM Bytes |
| Default       | TBD                     | TBD             |

## Functional Description

The Scanning SAR ADC Component is implemented on a hardware block that contains the following elements:

- SAR ADC
SAR ADC

Block Diagram
The SARADC core is a fast 12-bit ADC with SAR architecture. Preceding the SARADC is the SARMUX, which can route a combination of external pins and internal signals to inputs of the SARADC core. SARREF is a buffer used for multiple reference voltage selection. The SARSEQ sequencer block controls the SARMUX and the SARADC and does an automatic scan on all enabled channels as well as post-processing, such as averaging the output data.

Each channel has 16-bit conversion-result storage registers. At the end of the scan, a maskable interrupt is asserted. The sequencer also flags overflow and saturation errors that can be configured to assert an interrupt.

**Switched-capacitor filter**

**Block Diagram**

![Switched-capacitor filter diagram]

The switched-capacitor filter is an inverting 2\textsuperscript{nd}-order filter. To protect the analog ground (vagnd terminal) signal from disturbances on the SARMUX, it is first buffered by a half-CTB’s opamp set as a follower. Because the filter is inverting, vagnd is routed to the SAR’s positive terminal, and the filter output is routed to the negative terminal. Filter measurements are therefore made with the correct polarity.

The filter operates in two phases, and the output is only valid during the first. To ensure the filter measurement is always correct, the customizer configures the SAR and UAB specifically to synchronize the two, based on the initial parameters. **Any change to timing, such as disabling channels at runtime, may cause the SAR sample to desynchronize from the UAB’s valid output.**
Input Modes and Signedness

The input mode (S/E or Differential) determines the range of input voltages, and the signedness determines the digital codes to which the input range corresponds.

The smallest voltage in the range always corresponds to the lowest code.

The diagrams in this section show the various input ranges and their corresponding codes, represented in both 12-bit hexadecimal and decimal.

Note, it is recommended to use settings with intuitive results, such as S/E with Vneg = Vref and such as Signed Differential.
DMA Support

The DMA component can be used to transfer data from the component registers to RAM or another component.

<table>
<thead>
<tr>
<th>Name of DMA Source</th>
<th>Width</th>
<th>Direction</th>
<th>DMA Req Signal</th>
<th>DMA Trigger Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>Source</td>
<td>eoc</td>
<td>Pulse</td>
<td>Channel result data register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>This 32-bit register contains 16-bit ADC results.</td>
</tr>
</tbody>
</table>

* where X – is a channel number. The first channel is 0.

**Note** The component has a DMA bus interface that supports 32-bit (word) transfers only. If the data element size used for DMA transfer is less than a word, set the DMA descriptor with the correct width; for example, data element size is halfword (2 bytes). The component register is used as Source; make sure the DMA descriptor is configured as "Word to Halfword."

Registers

Channel result data registers

This 32-bit register contains 16-bit ADC results from channel 0 along with 3 status bits that describe the results correctness.

**ADC_SAR_CHAN_RESULT_REG**

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:0</td>
<td>Data</td>
<td>SAR conversion result of the first channel. The data is copied here from</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the work field after all enabled channels in this scan have been sampled.</td>
</tr>
<tr>
<td>29</td>
<td>ADC_SATURATE_INTR_MIR</td>
<td>Mirror bit of corresponding bit in ADC_SAR_SATURATE_INTR_REG register</td>
</tr>
<tr>
<td>30</td>
<td>ADC_RANGE_INTR_MIR</td>

</tr>
<tr>
<td>31</td>
<td>ADC_CHAN_RESULT_VALID_MIR</td>
<td>Mirror bit of corresponding bit in ADC_SAR_CHAN_RESULT_VALID_REG register</td>
</tr>
</tbody>
</table>

Result registers for the remaining channels are located sequentially in the memory. Direct defines for each channel are provided: ADC_SAR_CHANX_RESULT_REG, where X is the channel number from 0 to 7(15).
Interrupt request registers

Each of the interrupts described in this section has an interrupt mask in the ADC_SAR_INTR_MASK_REG register. By making the interrupt mask low, the corresponding interrupt source is ignored. The SAR interrupt is raised any time the intersection (logic AND) of the interrupt flags in ADC_SAR_INTR_REG registers and the corresponding interrupt masks in ADC_SAR_INTR_MASK_REG register is non zero.

When servicing an interrupt, the interrupt service routine (ISR) clears the interrupt source by writing a ‘1’ to the interrupt bit after picking up the related data.

For firmware convenience, the intersection (logic AND) of the interrupt flags and the interrupt masks are also made available in the SADC_SAR_INTR_MASKED_REG register.

**ADC_SAR_INTR_REG**

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ADC_EOS_MASK</td>
<td>End Of Scan Interrupt: hardware sets this interrupt after completing a scan of all the enabled channels. Write with ‘1’ to clear bit after picking up the data from the ADC_SAR_CHAN_RESULT_REG register.</td>
</tr>
<tr>
<td>1</td>
<td>ADC_OVERFLOW_MASK</td>
<td>Overflow Interrupt: hardware sets this interrupt when it sets a new ADC_EOS_MASK while that bit was not yet cleared by the firmware. Write with ‘1’ to clear bit.</td>
</tr>
<tr>
<td>2</td>
<td>ADC_FW_COLLISION_MASK</td>
<td>Firmware Collision Interrupt: hardware sets this interrupt when in <strong>Hardware trigger</strong> sample mode firmware triggers the conversion using ADC_StartConvert() API while the SAR is BUSY. Raising this interrupt is delayed to when the scan caused by the ADC_StartConvert() API has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the channels were sampled later than was intended (jitter). Write with ‘1’ to clear bit.</td>
</tr>
<tr>
<td>3</td>
<td>ADC_DSI_COLLISION_MASK</td>
<td>DSI Collision Interrupt: hardware sets this interrupt when the hardware SOC trigger signal is asserted while the SAR is BUSY. Raising this interrupt is delayed to when the scan caused by the hardware SOC trigger has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the channels were sampled later than was intended (jitter). Write with ‘1’ to clear bit.</td>
</tr>
</tbody>
</table>

These bits are enabled by the component by default in ADC_SAR_INTR_MASK_REG register and generate an interrupt.

Resources

The Scanning SAR ADC is implemented as a fixed-function block. The component also uses one Interrupt.

DC and AC Electrical Characteristics

Specifications are valid for $–40 \, ^\circ C \leq T_A \leq 85 \, ^\circ C$ and $T_J \leq 100 \, ^\circ C$, except where noted. Specifications are valid for 1.71 V to 5.5 V, except where noted.

**Note** Final characterization data for PSoC 4000S, PSoC 4100S and PSoC Analog Coprocessor devices is not available at this time. Once the data is available, the component datasheet will be updated on the Cypress web site.

Component Changes
This section lists the major changes in the component from the previous version.

<table>
<thead>
<tr>
<th>Version</th>
<th>Description of Changes</th>
<th>Reason for Changes / Impact</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.10</td>
<td>Added optional switched-capacitor filter to channel zero.</td>
<td>This feature provides additional signal processing before the ADC measurement.</td>
</tr>
<tr>
<td>1.0</td>
<td>Initial version of the component.</td>
<td>Final characterization data for PSoC 4000S, PSoC 4100S and PSoC Analog Coprocessor devices is not available at this time. Once the data is available, the component datasheet will be updated on the Cypress web site.</td>
</tr>
