

Objective

This code example demonstrates the functionality of the Capture feature of the Timer User Module of PSoC® 1.

Overview

Pulse width measurement is a feature needed in many embedded systems. There are several reasons to find the width of a given pulse. For example, one reason can be to measure the duration of a given event or to find the interval between the occurrences of two events.

There are different methods of Pulse Width Measurement, such as:

1. The timer capture method, which is discussed in this code example.
2. GPIO: Based on the GPIO interrupt that is generated whenever there is change in the GPIO state from last read by CPU.
3. Loads/starts the timer in the assembly code of GPIO_ISR while the next read stops the timer. Thereby, the pulse width can be calculated based on these values.

As shown in [Figure 1](#), the instances at which positive and negative edges occur for the test signal are recorded. The pulse width is calculated by finding the difference between these two values.

Figure 1. Test Signal whose Pulse Width needs to be Measure

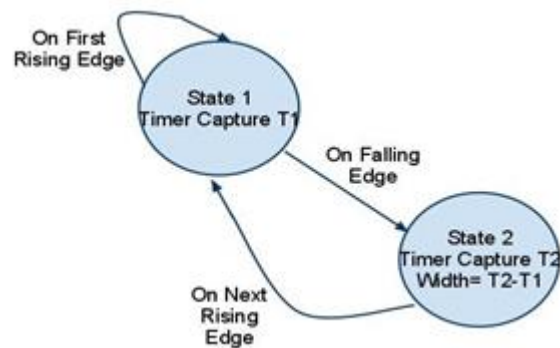

Principle

The principle of Pulse Width measurement can be understood by the simple state diagram shown in Figure 2. As seen from the figure, the system can be in any of the two states based on the edge of the test signal detected.

The 16-bit Timer is initially interrupted by the positive edge (which is the capture edge) of the test signal in State 1. The capture value is then stored and the edge is changed to negative edge (Negative edge detection by Timer).

During the subsequent negative edge, which follows when the FSM is in State 2, the capture value corresponding to the negative edge is stored and the difference is the pulse width of the signal. The Timer is now changed to positive edge capture and the cycle follows by going to State 1 on the next positive edge.

User Module List and Placement

This table lists the user modules used in this example and the hardware resources occupied by each user module.

User Module	Placement
Timer (16-bit)	DBB00 and DBB01
PWM (optional)	DCB02
LCD	Software

User Module Parameter Settings

These tables show the user module parameter settings for each user module used in the example.

Timer		
Parameter	Value	Comments
Clock	VC2	VC2 is used to generate a 1-MHz clock input to the Timer. This results in a resolution of measurement of 1 μ s
Period	65535	The period is set to 65535 to avoid any underflow between the two instances.
Capture	Row0 Input 2	The input signal is routed to the capture input from P0[2] through Row0_Input2
Interrupt Type	Capture	The timer generates an interrupt on a capture event
ClockSync	Sync to SysClk	As the clock to the timer is derived from SysClk, the clock sync is set to "SyncToSysClk"
PWM		
Parameter	Value	Comments
Clock	VC2	Clock source for PWM is VC2
Period	250	The period of the PWM generated signal set to 250, so that the output frequency is around 4 kHz. This is the test signal whose pulse width needs to be measured.
Pulsewidth	100	Test the pulse-width to be measured for verification
Compare type	Less than	Compare value should be less than the set threshold
ClockSync	Sync to SysClk	Clock should be synchronized to SysClk

LCD		
Parameter	Value	Comments
LCDPort	Port2	Port 2 is used for LCD connection
BarGraph	Disable	Bar graph feature is disabled

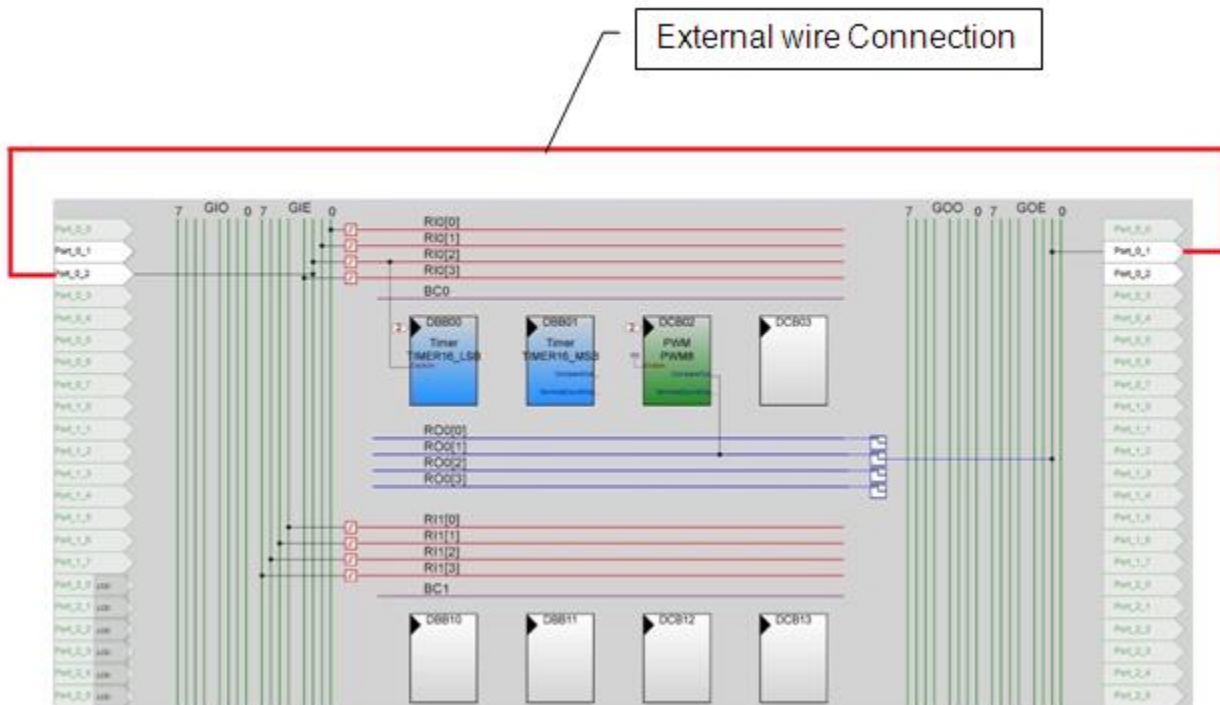

Notes

- Any of the associated part numbers for this example support the above resources and hence can be used to implement this design.
- The PWM is used only to generate a test signal to verify the operation. This can be avoided and a generic test signal from an external function generator can be used to feed input at P0.2. However, make sure the frequency of such a signal is within the measurable range (here the timer is fed by VC2 = 1 MHz, therefore the pulse frequency should be less than 1 MHz).

Global Resources

Important Global Resources		
Parameter	Value	Comments
VC1	12	$VC1 = 24 \text{ MHz}/12 = 2 \text{ MHz}$
VC2	2	$VC2 = VC1 / 2 = 1 \text{ MHz}$
CPU Clock	24 MHz	Sets CPU clock to 24 MHz

Chip View under PSoC Designer™

Hardware Connections

The Capture input to the Timer User Module is provided from P0.2. The test signal whose pulse width is to be measured is provided on P0.1 from the PWM User Module or by an external signal source.

Here the example is tested on the CY3210 – PSoC Eval1 board.

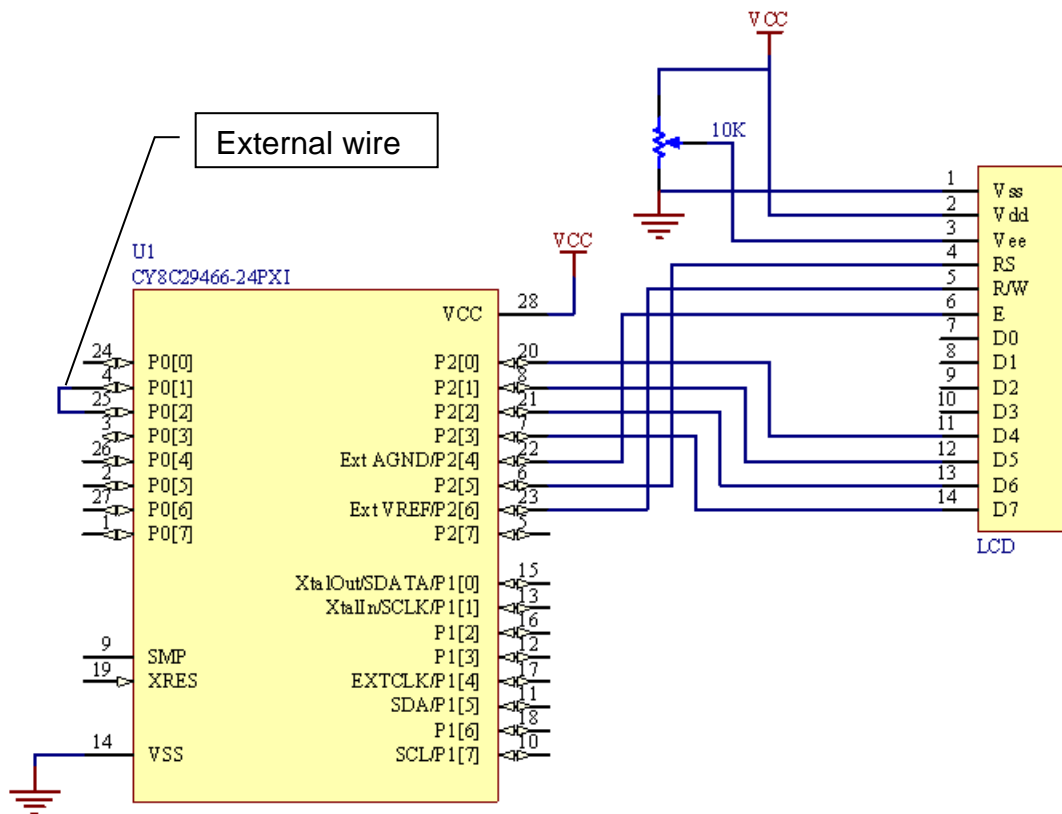

The hardware connection comprises of the following:

Connect wire between P0.1 to P0.2, which feeds the test signal generated in PSoC to the Timers for measurement.

Notes

- The CPU system clock frequency should be high when compared to the range of pulse width to be measured. This is because the edges from the test signal can be missed when the controller is servicing the Timer Capture ISR. Therefore, note that when this example is cloned for another chip, the CPU_clock should be fixed to SysClk/1.

The following schematic diagram shows the Pulse Width Measurement.

Operation

Figure 3. Functional Diagram of the Measurement Setup

Rising Edge Operation

Using the API `Timer_wReadCompareValue()`, the timer value at the moment of the rising edge is stored in the variable `CapturePosEdge`.

Using the statement, `Timer_FUNC_LSB_REG |= 0x80`; we set the 7th bit of the function register of the timer. By doing this, we change the capture type to falling edge. The falling edge flag is also set. Hence, the next time the interrupt is generated, the falling edge state is visited.

Falling Edge Operation

Using the API `Timer_wReadCompareValue()`, the timer value at the moment of the falling edge is stored into the variable `CaptureNegEdge`.

Using the statement, `Timer_FUNC_LSB_REG &= ~0x80`; we clear the 7th bit of the Function register of the timer. By doing this, we change the capture type to rising edge. The falling edge flag is cleared, the pulse width is calculated, and the data available flag is set.

Conclusion

The pulse width of the test signal is displayed on the LCD. In our case, 064 (hex equivalent of 100) is displayed on the LCD. To test the validity, one can vary the pulse width in the PWM User Module and program the PSoC again. This results in a new value being updated on the LCD during the next operation. Alternatively, any test signal whose pulse width needs to be measured can be fed to P0.2.

Upgrade Information

As the `ljmp` instruction to the C ISR for the Timer16 User Module is placed inside the user code markers inside the `TimerINT.asm` file, this change is preserved when the project is generated and built. If the source file for the `TimerINT.asm` file changes in a future release of PSoC Designer, this instruction may get overwritten. So, if you have upgraded PSoC Designer and find that this example is not working, check the following.

Open the `TimerINT.asm` file and check if there is an `'ljmp _TimerCaptureISR'` instruction present in the user code area in the `_Timer_ISR` function. If not, add this instruction within the user code markers.
