Please note that Cypress is an Infineon Technologies Company.
The document following this cover page is marked as “Cypress” document as this is the company that originally developed the product. Please note that Infineon will continue to offer the product to new and existing customers as part of the Infineon product portfolio.

Continuity of document content
The fact that Infineon offers the following product as part of the Infineon product portfolio does not lead to any changes to this document. Future revisions will occur when appropriate, and any changes will be set out on the document history page.

Continuity of ordering part numbers
Infineon continues to support existing part numbers. Please continue to use the ordering part numbers listed in the datasheet for ordering.

CE218553 – PSoC 6 MCU: PWM Triggering a DMA Channel

Objective

This code examples demonstrates how to route trigger signals on a PSoC 6 device. The trigger signal, in this code example, is routed from the PWM to the DMA, using PSoC Creator's auto routing feature.

Overview

This code example demonstrates how to route trigger signals in PSoC® 6. In this code example, PSoC Creator is used to configure the trigger multiplexer. This is demonstrated using a PWM trigger routed to a DMA channel. The PWM is connected to an LED to implement a variable intensity. The PWM also triggers the DMA in every cycle. The DMA is used to update the PWM duty cycle to create a breathing effect on the LED.

Requirements

Tool: PSoC Creator 4.2

Programming Language: C (ARM)

Associated Parts: All PSoC 6 MCU parts

Related Hardware: CY8CKIT-062 PSoC 6 BLE Pioneer Kit

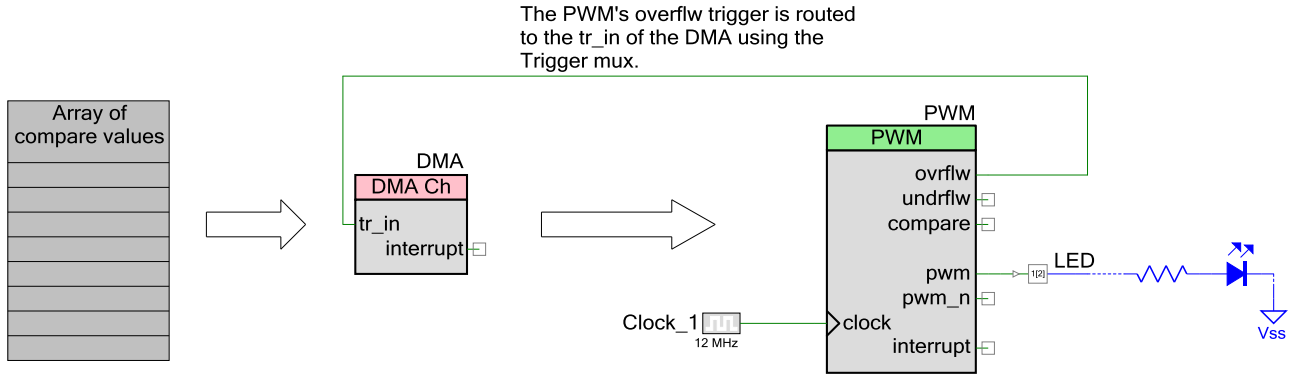
Design

The PSoC 6 device has many digital signals generated from different peripheral blocks. Many of these signals would need to be routed to other peripheral blocks as triggers to some events there. Trigger multiplexers are simple multiplexers that are designed to route these signals from potential source peripherals to destinations. This example demonstrates setting up a trigger route from the PWM to the DMA.

The design implements a PWM that has a duty cycle that is updated on every terminal count of the PWM through a DMA. There is a preset list of compare values in an array. These preset compare values are in a format that, when updated as the compare value of the PWM in every cycle, will generate a breathing pattern. The array with compare values is the source of data transfer for the DMA; the destination is the PWM's compare register. The DMA is triggered using the PWM's terminal count signal. The routing of the terminal count signal to the trigger input of the DMA is accomplished using the trigger multiplexer.

You need to connect the PWM overflow trigger (ovrflw) to the DMA input trigger (tr_in). The PSoC Creator build process takes care of generating the code responsible for routing the trigger signal. See Appendix A: Trigger Multiplexer Routing in PSoC Creator for more details on trigger multiplexer routing. Figure 1 shows the PSoC Creator project schematic.

Figure 1. PSoC Creator Project Schematic



Operation

1. Program the PSoC 6 device on CY8CKIT-062.
2. Observe the breathing pattern on the red LED in the kit.

   Note: In case of using any hardware other than CY8CKIT-062, use wires to connect the pin P0[3] to an LED.

Components

Table 1 lists the PSoC Creator Components used in this example, as well as the hardware resources used by each.

Table 1. PSoC Creator Components

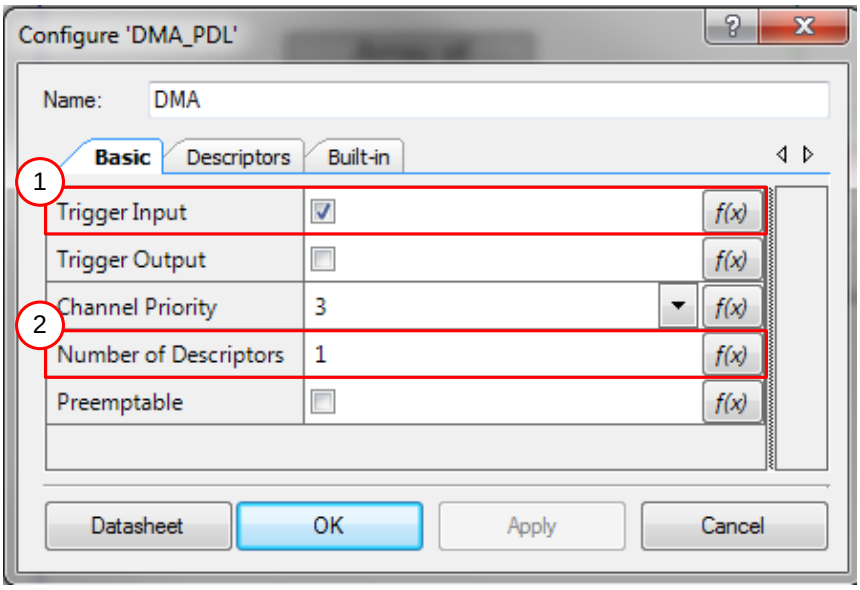
Component	Instance Name	Hardware Resources
DMA	DMA	1 DMA Channel
PWM	PWM	1 TCPWM block

Parameter Settings

DMA Configuration

A DMA channel is used to transfer the compare values from the array to the PWM compare register. Figure 2 shows the DMA Component's basic configuration.

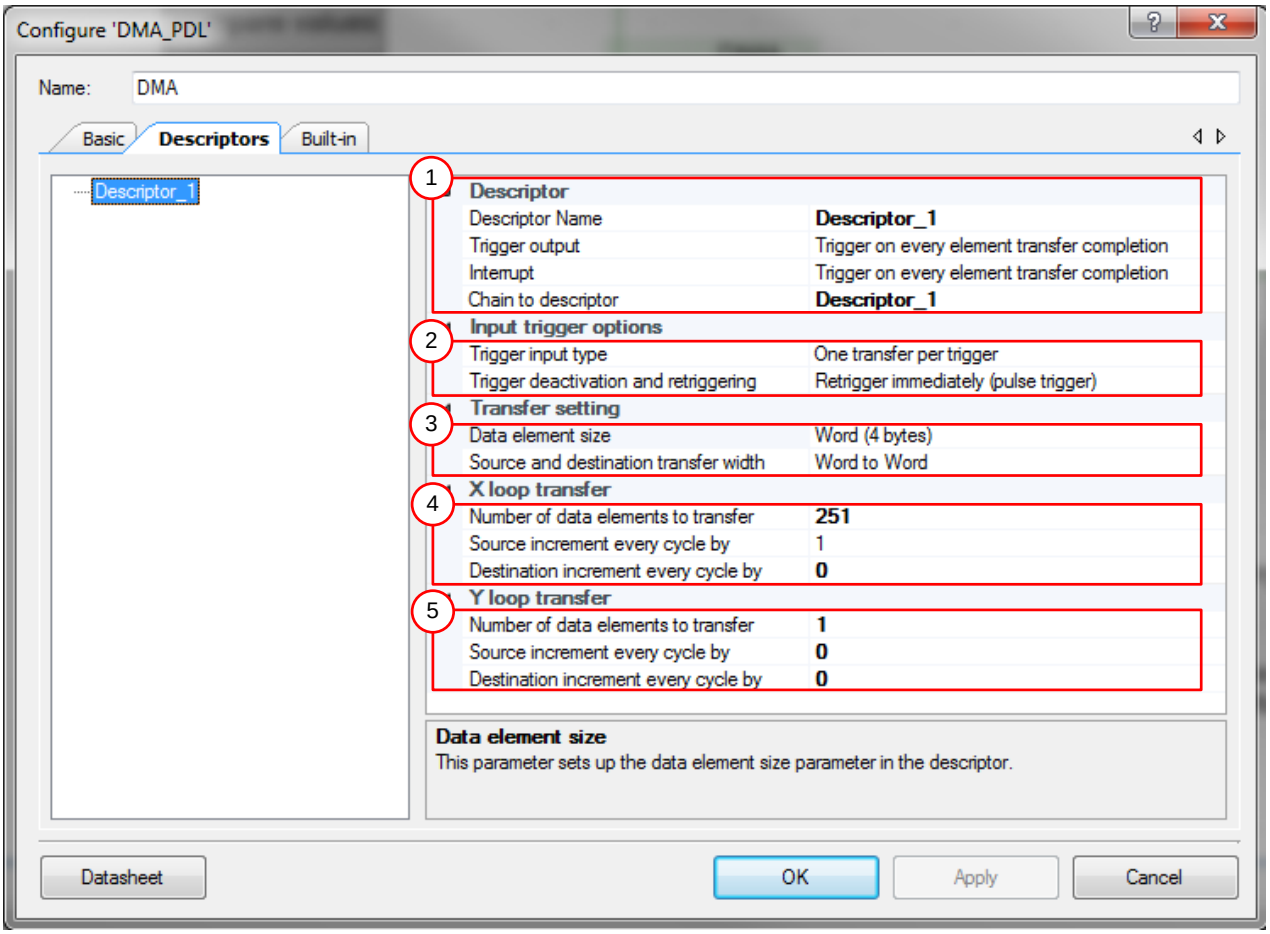
Figure 2. DMA Basic Configuration



1. The **trigger input** to the DMA is enabled so that a trigger signal routed through the trigger multiplexer block could be used to trigger the DMA channel. Enabling the trigger input provides a terminal on the DMA Component with a connection to a signal in the schematic.
2. The DMA is implementing a simple array to single register transfer, which can be achieved by using a single descriptor. The **number of descriptors** is set to 1.

Figure 3 shows the configuration of the DMA descriptor.

Figure 3. DMA Descriptor Configuration



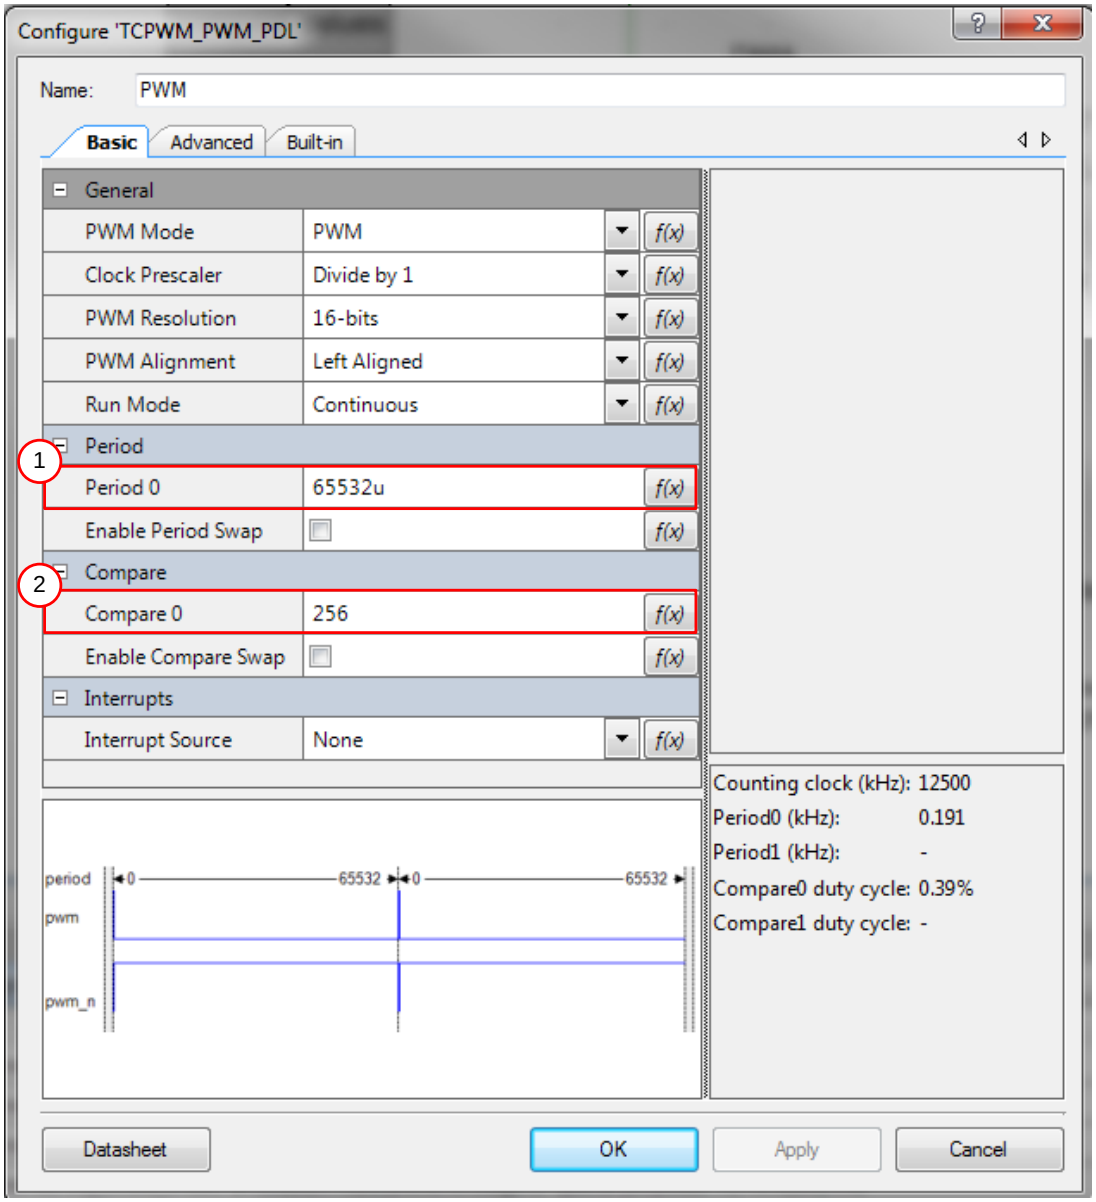
There is only one descriptor used for this DMA transfer. The descriptor configuration determines the characteristics of the DMA transfer.

1. The descriptor settings set up the name for the descriptor. These configurations also set the nature of the **trigger output** and **interrupt** outputs. These settings are left at their default settings because the trigger output or interrupt output are not used in this code example. The **chain to descriptor** is set as Descriptor_1, which will make the DMA execute the same descriptor in a loop.
2. The input trigger options determine how the descriptor handles trigger inputs. In this code example, the **trigger input type** is set to 'one transfer per trigger' because a single transfer from the array to compare register is required on every trigger generated by the terminal count.
3. Transfer settings are left at their default values. The **data size** is word (4 bytes) and the **source and destination transfer widths** are word-to-word because both the array and the compare register are 32-bit wide.
4. The X loop transfer setting sets up the x loop for the descriptor. The DMA can set up two nested loops of transfer; x loop is the inner loop of transfer. See the DMA Component datasheet for details. This descriptor transfers a 251-element array to a single compare register over 251 triggers. Therefore, the **number of data elements to transfer** is set as 251. Because the data source is an array, the address needs to be incremented after each transfer. Therefore, the **source increment every cycle by** 1. Because the destination is a constant compare register, **destination increment every cycle by** 0.
5. The Y loop is not utilized in this code example. Therefore, the number of data elements to transfer is set as 1. Both source and destination increments are set to 0.

PWM Configuration

The PWM configuration is shown in Figure 4.

Figure 4. PWM Configuration



Most of the PWM configurations except the period and compare values are left at their default values.

1. The period value of the PWM is set to 65532. The PWM is clocked by a 12-MHz clock and the terminal count is used to trigger the DMA. This period value (65532) makes sure that the terminal count and consequently the DMA trigger occurs at a frequency of 12/65532 MHz. The breathing rate of the LED will be determined by this rate of DMA trigger multiplied by the number of elements in the array of compare values.
2. The Compare value is set to 256 here. However, the compare value is updated later using this DMA. Therefore, this value starts the PWM at a very small duty cycle.

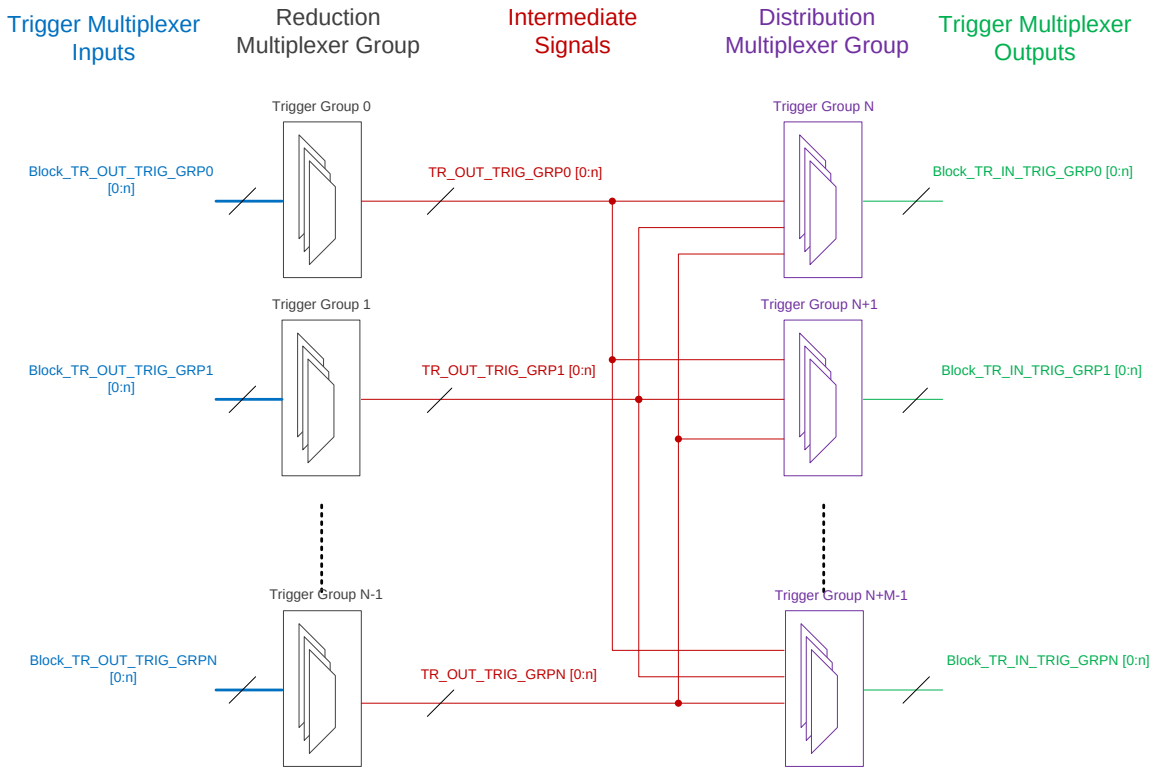
Appendix A: Trigger Multiplexer Routing in PSoC Creator

The PSoC 6 device has many digital signals generated from different peripheral blocks. Many of these signals would need to be routed to other peripheral blocks as triggers to some events there. Trigger multiplexers are simple multiplexers that are designed to route these signals from potential source peripherals to destinations.

The trigger multiplexer block is responsible for the entire trigger routing in the device. The trigger multiplexer block is implemented by using multiple trigger multiplexers. Trigger multiplexers are grouped into trigger multiplexer groups. There are multiple trigger multiplexer groups in a device, which combine to form the trigger multiplexer block. The trigger multiplexer block is architected into two layers. Each layer is formed by separate set of multiple trigger groups.

On the input side are the reduction trigger multiplexers and the output side are the distribution trigger multiplexers. A trigger signal route involves two multiplexer connections. First, the trigger multiplexer inputs are routed to intermediate signals using reduction multiplexers and then the intermediate signals are routed to relevant trigger multiplexer outputs using the distribution multiplexers.

Figure 5. Trigger Multiplexer Block Architecture



The routing of trigger multiplexers is achieved by configuring two trigger multiplexers per path. PSoC Creator's build process automatically generates the code required for trigger multiplexer routing. This trigger multiplexer routing code is in cyfitter_cfg.c, as a part of the CySystemInit (). The following code snippet is from the Cy_SystemInit() function of this code example and it shows the two Cy_TrigMux_Connect() calls to connect the two trigger multiplexers needed for the route.

```
/* Perform Trigger Mux configuration */
Cy_TrigMux_Connect(TRIG11_IN_TCPWM0_TR_OVERFLOW4, TRIG11_OUT_TR_GROUP0_INPUT15,
CY_TR_MUX_TR_INV_DISABLE, TRIGGER_TYPE_TCPWM_TR_OVERFLOW);

Cy_TrigMux_Connect(TRIG0_IN_TR_GROUP11_OUTPUT7, TRIG0_OUT_CPUSS_DW0_TR_IN1,
CY_TR_MUX_TR_INV_DISABLE, TRIGGER_TYPE_TR_GROUP_OUTPUT__LEVEL);
```

The first `Cy_TrigMux_Connect()` connects the TCPWM's overflow signal through a reduction multiplexer to an intermediate signal called "trigger 11" of trigger group 0. The second `Cy_TrigMux_Connect()` connects this intermediate trigger signal through a distribution multiplexer to the DMA's trigger input line.

For more information on the trigger multiplexer routing and architecture, see the Technical Reference Manual.
